Explicit modular towers

Noam D. Elkies

Abstract. We give a general recipe for explicitly constructing asymptotically optimal towers of modular curves such as $\{X_0(l^n)\}_{n>1}$. We illustrate the method by giving equations for eight towers with various geometric features. We conclude by observing that such towers are all of a specific recursive form and speculate that perhaps every tower of this form which attains the Drinfeld-Vlăduț bound is modular.

Introduction. Explicit equations for modular curves have attracted interest at least since the classical work of Fricke and Klein. Recent renewed interest in such equations has been stimulated on the one hand by the availability of software for symbolic computation and on the other hand by specific applications. In [E] we considered the use of modular curves to count rational points on elliptic curves over large finite fields, and illustrated some other applications of equations for the curves $X_0(N)$ with small N (say $N < 10^3$). Another kind of application is to coding theory: good Goppa codes [G] require curves of large genus g over a fixed finite field $k = \mathbb{F}_q$ whose number of rational points grows as a positive multiple of g . Drinfeld and Vlăduț showed that as $g \rightarrow \infty$ no multiple greater than $(q^{1/2} - 1)g$ is possible. Ihara [I] and, independently, Tsfasman, Vlăduț, and Zink [TVZ] showed that this upper bound is attained by the supersingular points on appropriate modular curves when q is a square. For this application modular curves — elliptic, Shimura, or Drinfeld — are needed whose level is too high to apply the methods of [E] directly, and in general one does not expect to have any pleasant model for a curve of high genus. However, if the curve is of smooth level then it tops a tower of $O(\log q)$ covers of low degree, and one may hope to obtain equations for the curve by writing those covers explicitly.

In this paper we show how to do this recursively for towers such as $\{X_0(l^n)\}_{n>1}$. It turns out that only information about the first few levels of the tower is needed, and that this information can be obtained for modular elliptic curves using the methods of [E], and for some Shimura curves using only the ramification structure. We then illustrate the method by giving explicit formulas for eight asymptotically optimal towers: six of elliptic modular curves, namely $X_0(l^n)$ for $l = 2, 3, 4, 5, 6$, and $X_0(3 \cdot 2^n)$; and two of Shimura modular curves. Over any finite field whose characteristic does not divide the level of these modular curves, the towers are tamely ramified, making it easy to calculate the genus of every curve in the tower. [This contrasts with the wildly ramified tower of [GS1], whose genus computation required some ingenuity; we show elsewhere that that tower too is modular, of Drinfeld type.] For each finite field k over which one of our towers is asymptotically optimal, the optimality can then be shown by elementary means, independent of the tower's modular provenance, by exhibiting the coordinates of the rational (supersingular) points. These formulas may also have other uses, e.g. in finding explicit modular parametrizations of elliptic curves with smooth conductor, or in connection with generalizations of the arithmetic-geometric mean (which corresponds to the $X_0(2^n)$ tower) as in [S1,S2]; we hope to pursue these connections in future papers. We conclude this paper with a speculation concerning the modularity of “any” asymptotically optimal tower.

The curves $X_0(l^n)$. Fix a prime $l > 1$. For positive n , the elliptic modular curve $X_0(l^n)$ over any field k in which $l \neq 0$ parametrizes elliptic curves with a cyclic l^n -isogeny, or equivalently sequences of l -isogenies

$$E_0 \rightarrow E_1 \rightarrow E_2 \rightarrow \cdots \rightarrow E_n \quad (1)$$

such that the composite isogeny $E_{j-1} \rightarrow E_{j+1}$ of degree l^2 is cyclic for each j with $0 < j < n$. Thus for each $m = 0, 1, \dots, n$ there are $n + 1 - m$ maps $\pi_j : X_0(l^n) \rightarrow X_0(l^m)$ obtained by extracting for some $j = 0, 1, \dots, n - m$ the cyclic l^m -isogeny $E_j \rightarrow E_{j+m}$ from (1). Each of these maps has degree l^{n-m} , unless $m = 0$ when the degree is $(l + 1)l^{n-1}$. In particular we have a tower of maps

$$X_0(l^n) \xrightarrow{\pi_0} X_0(l^{n-1}) \xrightarrow{\pi_0} X_0(l^{n-2}) \xrightarrow{\pi_0} \cdots \xrightarrow{\pi_0} X_0(l^2) \xrightarrow{\pi_0} X_0(l), \quad (2)$$

each map being of degree l . Each $X_0(l^n)$ also has an Atkin-Lehner involution $w_l = w_l^{(n)}$, taking a cyclic l^n -isogeny to its dual isogeny, and the sequence (1) to the sequence

$$E_n \rightarrow \cdots \rightarrow E_2 \rightarrow E_1 \rightarrow E_0 \quad (3)$$

of dual isogenies. We thus have

$$w_l^{(m)} \circ \pi_j = \pi_{n-m-j} \circ w_l^{(n)}, \quad (4)$$

where π_j, π_{n-m-j} are our j th and $(n - m - j)$ th maps from $X_0(l^n)$ to $X_0(l^m)$.

When $k = \mathbf{C}$, we may regard $X_0(N)$ as the quotient of the extended upper half-plane $\mathcal{H}^* = \mathcal{H} \cup \mathbf{P}^1(\mathbf{Q})$ by $\Gamma_0(N)$. Then the $\Gamma_0(l^n)$ orbit of a point $\tau \in \mathcal{H}$ parametrizes the isogeny between the elliptic curves with period lattices $\mathbf{Z} + \tau\mathbf{Z}$ and $l^{-n}\mathbf{Z} + \tau\mathbf{Z}$, the map π_j takes the $\Gamma_0(l^n)$ orbit of τ to the $\Gamma_0(l^m)$ orbit of $l^j\tau$, and the involution $w_l^{(n)}$ is represented by $\tau \longleftrightarrow -1/l^n\tau$.

Now the key observation is that explicit formulas for $X_0(l), X_0(l^2)$, together with the involutions $w_l^{(1)}, w_l^{(2)}$ of these curves and the map $\pi_0 : X_0(l^2) \rightarrow X_0(l)$ between them, suffice to exhibit the entire tower (2) explicitly:

Proposition. *For $n \geq 2$ the product map*

$$\pi = \pi_0 \times \pi_1 \times \pi_2 \times \cdots \times \pi_{n-2} : X_0(l^n) \rightarrow (X_0(l^2))^{n-1} \quad (5)$$

is a 1:1 map from $X_0(l^n)$ to the set of $(P_1, P_2, \dots, P_{n-1}) \in (X_0(l^2))^{n-1}$ such that

$$\pi_0(w_l^{(2)}(P_j)) = w_l^{(1)}(\pi_0(P_{j+1})) \quad (6)$$

for each $j = 1, 2, \dots, n - 2$.

Informally speaking, we get from $X_0(l^2)$ up to $X_0(l^n)$ by iterating $n - 2$ times the involution $w_l^{(2)}$ composed with the “ l -valued involution” $\pi_0^{-1}w_l^{(1)}\pi_0$. Of course the maps $\pi_j : X_0(l^n) \rightarrow X_0(l^m)$ (for $m \geq 2$) are then simply

$$(P_1, \dots, P_{n-1}) \mapsto (P_{j+1}, \dots, P_{j+m-1}), \quad (7)$$

and the involution $w_l^{(n)}$ is

$$(P_1, P_2, \dots, P_{n-2}, P_{n-1}) \longleftrightarrow (w_l^{(2)}P_{n-1}, w_l^{(2)}P_{n-2}, \dots, w_l^{(2)}P_2, w_l^{(2)}P_1), \quad (8)$$

i.e. reversing the order of P_1, \dots, P_{n-1} and applying $w_l^{(2)}$ to each coordinate.

*Proof*¹: That the map is 1:1 to its image is clear, because a sequence (1) of l -isogenies is determined by the l^2 -isogenies $E_{j-1} \rightarrow E_{j+1}$ parametrized by the j th coordinate of π ($0 < j < n$). Now (P_1, \dots, P_{n-1}) is in the image of π if and only if the l^2 -isogenies parametrized by P_1, \dots, P_{n-1} , regarded as sequences $E_0^j \rightarrow E_1^j \rightarrow E_2^j$ of l -isogenies, fit together to form a sequence (1) with $E_i^j = E_{i+j}$, i.e. if and only if the isogenies $E_1^j \rightarrow E_2^j$ and $E_0^{j+1} \rightarrow E_1^{j+1}$ coincide for each $j = 1, 2, \dots, n-2$. But these isogenies are represented by the points $\pi_1(P_j)$ and $\pi_0(P_{j+1})$ on $X_0(l)$. Thus the necessary and sufficient condition is that

$$\pi_1(P_j) = \pi_0(P_{j+1}) \quad (9)$$

for each $j = 1, 2, \dots, n-2$; applying $w_l^{(1)}$ to both sides, and then (4) to $w_l^{(1)}(\pi_1(P_j))$, then yields the equivalent form (6). \square

Examples: The cases $l = 2, 3, 5$. Our formulas are particularly simple when $X_0(l^2)$ (and thus also $X_0(l)$) has genus 0, for then we may use a Hauptmodul (or for that matter any rational parameter²) of $X_0(l^2)$ to regard P_1, \dots, P_{n-1} as $n-1$ rational coordinates on $X_0(l^n)$, and (6) as the $n-2$ algebraic relations on those coordinates that determine the curve $X_0(l^n)$. This happens for $l = 2, 3, 5$; we exhibit formulas for each of these cases.

In the first two cases the cover $\pi_0 : X_0(l^2) \rightarrow X_0(l)$ is cyclic.³ For $l = 2$ we parametrize $X_0(l^2) = X_0(4)$ by

$$\xi(\tau) := 1 + \frac{1}{8} \left(\frac{\eta(\tau)}{\eta(4\tau)} \right)^8 = \frac{1}{8} (q^{-1} + 20q - 62q^3 + 216q^5 - 641q^7 + \dots), \quad (10)$$

where as usual $q = e^{2\pi i \tau}$ and η is the weight- $\frac{1}{2}$ modular form $\prod_{r=1}^{\infty} (1 - q^r)$. Using the functional equation

$$\eta(-1/\tau) = (\tau/i)^{1/2} \eta(\tau), \quad (11)$$

we find that the involution $w_2^{(2)}$ takes $\xi(\tau)$ to

$$\xi(-1/4\tau) = 1 + 32 \left(\frac{\eta(4\tau)}{\eta(\tau)} \right)^8 = 1 + \frac{4}{\xi(\tau) - 1} = \frac{\xi(\tau) + 3}{\xi(\tau) - 1}. \quad (12)$$

Let h_2 be the $X_0(2)$ Hauptmodul

$$h_2(\tau) = \left(\frac{\eta(\tau)}{\eta(2\tau)} \right)^{24} = q^{-1} - 24 + 276q - 2048q^2 + 11202q^3 - \dots \quad (13)$$

¹ More properly, a proof sketch, since we suppress some details, such as what happens at the cusps. To show that our formulas extend to the cusps one may either quote general facts about maps between affine and projective algebraic curves, or regard the cusps as parametrizing isogenies between Tate curves. Also, two cyclic l -isogenies may determine the same point on $X_0(l)$ without being isomorphic; the necessary and sufficient condition is that they become isomorphic over the algebraic closure.

² A ‘‘Hauptmodul’’ is a rational parameter with a pole of leading coefficient 1 at the infinite cusp, i.e. a degree-1 rational function of the form $q^{-1} + O(1)$.

³ For any N , the cover $\pi_0 : X_0(N^2) \rightarrow X_0(N)$ is cyclic if and only if the unit group of $\mathbf{Z}/N\mathbf{Z}$ has exponent 2, which happens when $N|24$. When $N = 1, 2, 3, 4, 6$, it is furthermore true that ± 1 are the only units of $\mathbf{Z}/N\mathbf{Z}$, and then the cyclic N -isogenies $E_1 \rightarrow E_0, E_2$ together with the Weil pairing on $E_1[N]$ determine a complete level- N structure on $E_1 \bmod \pm 1$, i.e. $X_0(l^2) \cong X(l)$.

Computing the map $\pi_0 : X_0(4) \rightarrow X_0(2)$ then amounts to writing h_2 as a rational function in ξ . We do this by in effect expanding this function as a continued fraction. Necessarily that function has degree 2 with a simple pole at the cusp $\xi = \infty$. But then $h_2 - 8\xi + 24$ is a rational function of degree 1 in ξ with a simple zero at ∞ , i.e. the inverse of a polynomial of degree 1. Comparing the q -expansions of $1/(h_2 - 8\xi + 24)$ and ξ , we find that this polynomial is $(\xi + 1)/32$ and recover the formula

$$h_2(\tau) = 8 \frac{(\xi(\tau) + 1)^2}{(\xi(\tau) - 1)}. \quad (14)$$

Using our formula (12) for the involution $w_2^{(2)}$ we then obtain also

$$h_2(\tau) = \frac{64}{\xi(-1/4\tau)^2 - 1}. \quad (15)$$

But $w_2^{(1)}$ acts on $X_0(2)$ by $h_2 \leftrightarrow 2^{12}/h_2$ (again by (11)). Thus $h_2(2\tau)$ is both $64(\xi(\tau)^2 - 1)$ and $64/(\xi(-1/8\tau)^2 - 1)$. Equating these two expressions yields an equation for the modular curve $X_0(8)$; more generally we now deduce from our Proposition the following explicit equations for the modular curve $X_0(2^n)$ for each $n > 1$:

Let x_j ($0 < j < n$) be the rational function $\xi(2^{j-1}\tau)$ on that curve (this is the coordinate P_j of the Proposition); then (x_1, \dots, x_{n-1}) identifies $X_0(2^n)$ with the curve in $(\mathbf{P}^1)^{n-1}$ specified by the $n - 2$ equations

$$(x_j^2 - 1)(z_{j+1}^2 - 1) = 1 \quad (j = 1, \dots, n - 2), \quad (16)$$

where

$$z_j := (x_j + 3)/(x_j - 1) \quad (17)$$

is obtained from x_j by the involution $w_2^{(2)}$.

Curiously we obtain analogous equations for $X_0(3^n)$ by replacing the exponent 2 by 3 in (16) and, as if to compensate, changing the constant term 3 to 2 in (17): the curve $X_0(3^n)$ is isomorphic with the locus of (x_1, \dots, x_{n-1}) in $(\mathbf{P}^1)^{n-1}$ satisfying

$$(x_j^3 - 1)(z_{j+1}^3 - 1) = 1 \quad (j = 1, \dots, n - 2), \quad (18)$$

where

$$z_j := (x_j + 2)/(x_j - 1). \quad (19)$$

Here the coordinate functions x_j on $X_0(3^n)$ are $\xi(3^{j-1}\tau)$, where

$$\xi(\tau) = 1 + \frac{1}{3} \left(\frac{\eta(\tau)}{\eta(9\tau)} \right)^3 = \frac{1}{3} (q^{-1} + 5q - 7q^5 + 3q^8 + 15q^{11} - 32q^{14} \dots), \quad (20)$$

so ξ generates the field of rational functions on $X_0(9)$. The involution $w_3^{(2)}$ takes this ξ to $1 + 3/(\xi - 1) = (\xi + 2)/(\xi - 1)$, whence (19); the Hauptmodul

$$h_3(\tau) = \left(\frac{\eta(\tau)}{\eta(3\tau)} \right)^{12} = q^{-1} - 12 + 54q - 76q^2 - 243q^3 + 1188q^4 \dots \quad (21)$$

goes to $3^6/h_3$ under $w_3^{(1)}$, and $h_3(3\tau)$ is both $27/(\xi(-1/27\tau)^3 - 1)$ and $27(\xi(\tau)^3 - 1)$, from which the equations (18,19) for $X_0(3^n)$ follow thanks to our Proposition.

Note that the already simple equations for $X_0(2^k)$, $X_0(3^k)$ simplify even further in characteristic 3, 2 respectively: taking $y_j = 1 - x_j^{-1}$ in (16,17) and setting $3 = 0$ yields

$$y_{j+1}^2 = y_j - y_j^2, \quad (22)$$

and the same substitution in (18,19) with $2 = 0$ produces

$$y_{j+1}^3 = y_j^3 + y_j^2 + y_j. \quad (23)$$

In this guise these asymptotically optimal towers were obtained by Garcia and Stichtenoth [GS2, Examples C,D], independent (as in [GS1]) of their modular interpretation. In both cases the supersingular points are the poles of y_1 and thus of all the y_j .

Finally for $l = 5$ we obtain

$$P(x_j)P(z_{j+1}) = 125 \quad (j = 1, \dots, n-2), \quad (24)$$

where

$$P(X) := X^5 + 5X^3 + 5X - 11, \quad z_j := (x_j + 4)/(x_j - 1). \quad (25)$$

Here the coordinate x_j is $\xi(5^{j-1}\tau)$ where

$$\xi(\tau) = 1 + \frac{\eta(\tau)}{\eta(25\tau)} = q^{-1} - q + q^4 + q^6 - q^{11} - q^{14} + q^{21} + q^{24} - q^{26} \dots \quad (26)$$

As usual, z_j is the image of x_j under $w_l^{(2)}$, and $P(x_j) = h_5(5\tau)$ where h_5 is the $X_0(5)$ Hauptmodul

$$h_5(\tau) = \left(\frac{\eta(\tau)}{\eta(5\tau)} \right)^6 = q^{-1} - 6 + 9q + 10q^2 - 30q^3 + 6q^4 - 25q^5 \dots \quad (27)$$

with $h_5(\tau)h_5(-1/5\tau) = 125$. The polynomial $P(X)$ is necessarily not as simple as the polynomials $X^2 - 1$, $X^3 - 1$ occurring in (16,18), because the cover $X_0(25) \rightarrow X_0(5)$ is not cyclic. It is, however, dihedral, as may be seen from the fact that $P(W - 1/W) = W^5 - 11 - W^{-5}$.

First variation: composite l . The assumption that l be prime was not necessary; the entire description carries over to the composite case, except for the incidental point that the degree of the maps $\pi_j : X_0(l^n) \rightarrow X(1)$ is given by a formula more complicated than $(l+1)l^{n-1}$ [namely $l^n \prod_{p|l} (1 + \frac{1}{p})$]. For instance we exhibit formulas for the cases $l = 4, 6$, where the cover $\pi_0 : X_0(l^2) \rightarrow X_0(l)$ is still cyclic.

In the first case $l = 4$ the curve $X_0(l^2) = X_0(16)$ is still rational, and we obtain formulas remarkably similar to those for $l = 2, 3$ by choosing

$$\xi(\tau) = 1 + \frac{1}{2} \frac{\eta^2(\tau)\eta(8\tau)}{\eta(2\tau)\eta^2(16\tau)} = \frac{1}{2}(q^{-1} + 2q^3 - q^7 - 2q^{11} + 3q^{15} + 2q^{19} \dots) \quad (28)$$

as a rational coordinate on $X_0(16)$. Then $w_4^{(2)}$ takes ξ to $(\xi+1)/(\xi-1)$. The $X_0(4)$ Hauptmodul

$$h_4(\tau) = \left(\frac{\eta(\tau)}{\eta(4\tau)} \right)^8 = q^{-1} - 8 + 20q - 62q^3 + 216q^5 - 641q^7 + \dots \quad (29)$$

(cf. (10)) is mapped by $w_4^{(1)}$ to $4^4/h_4$, and we compute

$$h_4(4\tau) = \frac{16}{\xi(-1/64\tau)^4 - 1} = 16(\xi(\tau)^4 - 1). \quad (30)$$

Therefore $X_0(4^n)$ is isomorphic with the locus of (x_1, \dots, x_{n-1}) in $(\mathbf{P}^1)^{n-1}$ satisfying

$$(x_j^4 - 1)(z_{j+1}^4 - 1) = 1 \quad (j = 1, \dots, n-2), \quad (31)$$

where

$$z_j := (x_j + 1)/(x_j - 1), \quad (32)$$

the coordinate functions x_j on $X_0(4^n)$ being $\xi(4^{j-1}\tau)$. Of course the resulting curves also occur in the $X_0(2^n)$ tower, but this fact is far from obvious from comparison of the formulas (16,17) and (31,32).

The case of $l = 6$ is slightly more complicated because the curve $X_0(l^2)$ is no longer rational. It is, however, an elliptic curve with a simple Weierstrass equation: the ring of rational functions on $X_0(36)$ regular except possibly at the cusp $\tau = i\infty$ is generated by

$$\xi(\tau) = \frac{\eta(12\tau)\eta^3(18\tau)}{\eta(6\tau)\eta^3(36\tau)} = q^{-2} + q^2 + q^8 - q^{14} - q^{20} + q^{26} + 2q^{32} \dots, \quad (33)$$

$$\gamma(\tau) = \frac{\eta^4(12\tau)\eta^2(18\tau)}{\eta^2(6\tau)\eta^4(36\tau)} = q^{-3} + 2q^3 + q^9 - 2q^{15} - 2q^{21} + 2q^{27} + 4q^{33} \dots, \quad (34)$$

related by the Weierstrass equation

$$\gamma^2 = \xi^3 + 1. \quad (35)$$

The involution $w_6^{(2)}$ has a fixed point at $i/6$. An involution of an elliptic curve which has a fixed point must be multiplication by -1 composed with a translation. Thus to determine $w_6^{(2)}$ we need only find the image of one point. It is easiest to do this with the cusp $\tau = i\infty$: its image is the cusp $\tau = 0$, at which $(\xi, \gamma) = (2, 3)$ (a 6-torsion point on the curve (35)). It remains only to find the map from $X_0(36)$ to $X_0(6)$ and the involution $w_6^{(1)}$. We use the Hauptmodul

$$h_6(\tau) = \frac{\eta^5(\tau)\eta(3\tau)}{\eta(2\tau)\eta^5(6\tau)} = q^{-1} - 5 + 6q + 4q^2 - 3q^3 - 12q^4 - 8q^5 + 12q^6 \dots \quad (36)$$

Then $w_6^{(1)}$ takes h_6 to $72/h_6$, and by comparing q -expansions we find

$$h_6(6\tau) = \xi^3(\tau) - 8. \quad (37)$$

We thus identify $X_0(6^n)$ with the curve of $(n-1)$ -tuples $((x_1, y_1), \dots, (x_{n-1}, y_{n-1}))$ of points on the elliptic curve $y^2 = x^3 + 1$ satisfying the $n-2$ conditions

$$(x_j^3 - 8)(z_{j+1}^3 - 8) = 72 \quad (j = 1, \dots, n-2), \quad (38)$$

where

$$z_j := \left(\frac{y_j + 3}{x_j - 2} \right)^2 - x_j - 2 \quad (39)$$

is the x -coordinate of the point $(2, 3) - (x, y)$ on $y^2 = x^3 + 1$. Unlike the curves in the $X_0(4^n)$ tower, these curves $X_0(6^n)$ are new; to be sure they could also be exhibited as composita of

the already known covers $X_0(2^n)/X(1)$ and $X_0(3^n)/X(1)$, but those models are much harder to work with because of the complicated singularities above the branch points $j = 0, 12^3, \infty$.

Second variation: changing the base of the tower. Instead of the tower of modular curves $X_0(l^n) = \mathcal{H}^*/\Gamma_0(l^n)$ we could use $\mathcal{H}^*/(\Delta \cap \Gamma_0(l^n))$ where Δ is some other congruence subgroup of $\mathrm{PGL}_2(\mathbf{Q})$, as long as the modulus of the congruence is prime to l . For instance, given $N > 1$ with $(l, N) = 1$ we could use the tower $X_0(Nl^n)$ of curves parametrizing sequences of l -isogenies between pairs of elliptic curves related by a cyclic N -isogeny. Again these curves with $n > 1$ form a tower related by maps π_j of l -power degree and admitting involutions $w_l^{(n)}$, and knowing these maps and involutions for $n = 1, 2$ yields explicit formulas for $X_0(Nl^n)$ for all $n > 1$ as in our Proposition.⁴

We illustrate with the case $l = 2, N = 3$. In this case the first two curves $X_0(6), X_0(12)$ are rational and we can mimic our procedure for the towers $X_0(l^n)$ with $l = 2, 3, 4$. Our $(n - 1)$ coordinates on $X_0(3 \cdot 2^n)$ will be $x_j = \xi(2^{j-1}\tau)$ ($0 < j < n$) where

$$\xi(\tau) = \frac{\eta^4(4\tau)\eta^2(6\tau)}{\eta^2(2\tau)\eta^4(12\tau)} = q^{-1} + 2q + q^3 - 2q^5 - 2q^7 + 2q^9 + 4q^{11} \dots \quad (40)$$

(cf. (34)) is a Hauptmodul for $X_0(12)$. It is this time more convenient to let h_6 be the $X_0(6)$ Hauptmodul

$$h_6(\tau) = \left(\frac{\eta(2\tau)\eta^3(3\tau)}{\eta(\tau)\eta^3(6\tau)} \right)^3 = q^{-1} + 3 + 6q + 4q^2 - 3q^3 - 12q^4 - 8q^5 \dots, \quad (41)$$

which differs by 8 from our choice in (36). We may then represent $w_2^{(1)}$ and $w_2^{(2)}$ by $\tau \longleftrightarrow (2\tau - 1)/(6\tau - 2)$ and $\tau \longleftrightarrow (4\tau + 3)/(4\tau + 4)$; these involutions take h_6 to $-8/h_6$ and ξ to $(3 - \xi)/(1 + \xi)$. By computing the quadratic map $X_0(12) \rightarrow X_0(6)$ we find that this time

$$h_6(2\tau) = \frac{-8}{\xi(w_2^{(2)}\tau)^2 - 1} = \xi(\tau)^2 - 1. \quad (42)$$

Thus the equations on x_1, \dots, x_{n-1} defining $X_0(3 \cdot 2^n)$ are

$$(x_j^2 - 1)(z_{j+1}^2 - 1) = -8 \quad (j = 1, \dots, n - 2), \quad (43)$$

where

$$z_j := (3 - x_j)/(1 + x_j). \quad (44)$$

Note that in this case the curves in our tower also have an involution w_3 commuting with all the $w_2^{(n)}$; we find that this involution is $x_j \leftrightarrow -3/x_j$. That this in fact acts on our model of $X_0(3 \cdot 2^n)$ is easy to check after writing (43,44) in the equivalent form

$$(x_{j+1} - 1)x_j^2 = x_{j+1}^2 + 3x_{j+1}. \quad (45)$$

⁴ As with $X_0(6^n)$ we could also obtain $X_0(Nl^n)$ as a compositum of $X_0(N)$ and $X_0(l^n)$, but the resulting model is highly singular. Warning: on $X_0(Nl^n)/\mathbf{C}$ the involution $w_l^{(n)}$ is given not by $\tau \leftrightarrow -1/l^n\tau$ but by a fractional linear transformation of the same determinant that reduces mod N to an element of $\Gamma_0(N)$. We do still have a simple formula $\tau \leftrightarrow -1/Nl^n\tau$ for the product of $w_l^{(n)}$ with the Atkin-Lehner involution w_N .

Third variation: Shimura modular curves. Shimura curves generalize the classical elliptic modular curves: instead of \mathcal{H}^*/Γ for an arithmetic subgroup Γ of $\mathrm{PGL}_2(\mathbf{Q})$, they are the quotients \mathcal{H}/Γ by an arithmetic subgroup of a quaternion algebra A over some totally real number field K , with A ramified at all but one of the infinite places of K . Instead of elliptic curves, these Shimura curves parametrize principally polarized abelian varieties with endomorphisms by A and some extra structure determined by the choice of Γ . There are Shimura curves $\mathcal{X}_0(I)$ (I an ideal of K coprime with the discriminant of A) analogous to $X_0(N)$, which have Atkin-Lehner involutions and form towers, and whose reductions at a prime of K are asymptotically optimal over the quadratic extensions of its residue field. These towers may be obtained from their first two levels by the recipe of our Propositions.

Unlike the classical $X_0(N)$, the analogous Shimura curves $\mathcal{X}_0(I)$ have no cusps. Thus the curves and maps between them cannot be computed using q -expansions. Even worse, in general we do not even have explicit equations for the abelian varieties parametrized by these curves. Nevertheless we can in many cases use the ramification behavior of the covers to determine the necessary maps completely. We illustrate this with two examples which have the additional feature of involving only cyclic covers which become unramified after finitely many steps and thus also occur in class-field towers.⁵

We start with K, A such that A^* contains an arithmetic subgroup Δ which is also a triangle group. Such Δ have been classified completely [T]: there are 76, in 18 quaternion algebras (not including the nine triangle subgroups of $\mathrm{PGL}_2(\mathbf{Q})$ with one or more cusps among the vertices). For our first example we take $K = \mathbf{Q}(\sqrt{3})$ and A/K = the quaternion algebra ramified at $(\sqrt{3})$ and at one infinite place, and choose for Δ the group called $\Gamma^{(+)}(A, O_1) = \Gamma^{(*)}(A, O_1)$ in [T], which is identified there with the $(2, 4, 12)$ triangle group. We shall construct the tower $\{\mathcal{X}_0(\wp_2^n)\}_{n>1}$, where \wp_2 is the prime of K of residue field \mathbf{F}_2 .

The curve $\mathcal{X}(1) = \mathcal{H}/\Delta$ is rational. We choose a coordinate J taking the values $1, 0, \infty$ at the elliptic points of order $2, 4, 12$. The curve $\mathcal{X}_0(\wp_2)$ consists of ordered pairs of points of $\mathcal{X}(1)$ related by a “ \wp_2 -isogeny”; choosing one of these points yields the degree-3 map $\pi_0 : \mathcal{X}_0(\wp_2) \rightarrow \mathcal{X}(1)$. We next determine the ramification of this map. In general, the map $\mathcal{X}_0(I) \rightarrow \mathcal{X}(1)$ is branched only above elliptic points of $\mathcal{X}(1)$, if a point P of $\mathcal{X}_0(I)$ above an elliptic point of order e parametrizes an isogeny to some other point of order e' then the ramification index at P is the denominator of the fraction e'/e . [A non-elliptic point is taken to have order 1.] We may regard $\mathcal{X}_0(\wp_2)$ as a symmetric $(3, 3)$ correspondence on $\mathcal{X}(1) \times \mathcal{X}(1)$. We then see that the point $J = \infty$ of order 12 must correspond to the point $J = 0$ of order 4 with multiplicity 3; the point $J = 0$ corresponds to $J = 1$ doubly and $J = \infty$ singly; and $J = 1$ corresponds to $J = 0$ singly and some other point doubly. No other points of $\mathcal{X}(1)$ are ramified in $\mathcal{X}_0(\wp_2)$. Thus by the Riemann-Hurwitz formula $\mathcal{X}_0(\wp_2)$ is again a rational curve, and J is a function of degree 3 with a triple pole such that J and $J - 1$ both have double zeros. Up to $\mathrm{Aut}(\mathbf{P}^1)$ there is a unique such function; we choose a rational coordinate t on $\mathcal{X}_0(\wp_2)$ such that $J = t(4t - 3)^2$ (so $J - 1 = (t - 1)(4t - 1)^2$). Then the involution⁶ $w^{(1)}$ must interchange the points $t = 0$, $t = \infty$ parametrizing isogenies between $J = 0$ and $J = \infty$, and the points $t = 1$, $t = 3/4$

⁵ Note that this is not possible with elliptic modular curves, or for that matter with Drinfeld modular curves, precisely because of their cusps. However, the ramification in towers of elliptic or Drinfeld modular curves is small enough to be captured by a tower of ray class fields, suggesting that ray class-field towers might be a fruitful source of curves with many points even over finite fields of non-square order.

⁶ We suppress the unwieldy subscript \wp_2 .

parametrizing isogenies between $J = 0$ and $J = 1$. Therefore $w^{(1)}(t) = 3/4t$.

Now the curve $\mathcal{X}_0(\wp_2^2)$ covers $\mathcal{X}_0(\wp_2)$ with degree 2, and the only branch points are $t = \infty$ and $t = 3/4$. Thus $\mathcal{X}_0(\wp_2^2)$ is again a rational curve, and we may choose a rational coordinate ξ for it such that $t = (\xi^2 + 3)/4$. Of the points $\xi = \pm 1$ above $t = 1$, one must parametrize a \wp_2^2 -isogeny from $J = 1$ to $J = \infty$, the other an isogeny from $J = 1$ to itself; we choose ξ so the former point is $\xi = 1$. Then $w^{(2)}$ must switch that point with the point $\xi = \infty$, and fix the other point $\xi = -1$; therefore this involution is $\xi \longleftrightarrow (\xi + 3)/(\xi - 1)$. As a further check on the computation, note that this involution also switches the two points $\xi = \pm\sqrt{-3}$ above $t = 0$, parametrizing a \wp_2^2 -isogeny from $J = 0$ to itself.

We now have all the information needed to determine the Shimura modular curve $\mathcal{X}_0(\wp_2^n)$ for all $n > 1$: that curve has $n - 1$ coordinates x_1, \dots, x_{n-1} , satisfying the $n - 2$ relations

$$\left(\frac{x_j^2 + 3}{4}\right) \left(\frac{z_{j+1}^2 + 3}{4}\right) = \frac{3}{4}, \quad (46)$$

that is,

$$(x_j^2 + 3)(z_{j+1}^2 + 3) = 12 \quad (j = 1, \dots, n - 2), \quad (47)$$

where

$$z_j := (x_j + 3)/(x_j - 1), \quad (48)$$

the same involution we used in (17) for the tower of classical modular curves $X_0(2^n)$. Unlike these curves, though, the Shimura tower $\mathcal{X}_0(\wp_2^n)$ turns out to be unramified past $n = 5$, as may be seen either directly from the formulas (47,48) or from the general description of ramification in the map $\mathcal{X}_0(I) \rightarrow \mathcal{X}(1)$. Since each step in the tower is a cyclic extension, it follows that over any finite field of odd characteristic the tower is dominated by the 2-class-field tower of the curve $\mathcal{X}_0(\wp_2^5)$.

For our second example, we choose for K the cubic field $\mathbf{Q}(2 \cos \pi/9)$ and for A the quaternion algebra ramified only at two of the three infinite places of K . Then we find in [T] that the group of units of norm 1 in A is the $(2, 3, 9)$ triangle group. We exhibit the tower $\{\mathcal{X}_0(\wp_3^n)\}_{n>1}$, where \wp_3 is the prime of K of residue field \mathbf{F}_3 . The equations were obtained in the same way that we found (47,48); we leave the intermediate steps as an exercise. Again we find formulas similar to those we obtained earlier (18,19) for the classical modular curves: there are $n - 1$ coordinates x_1, \dots, x_{n-1} , related by $n - 2$ equations

$$x_j^3 + z_{j+1}^3 = 1 \quad (j = 1, \dots, n - 2) \quad (49)$$

(this time even simpler than the equation (18) for the classical case), where again

$$z_j := (x_j + 2)/(x_j - 1). \quad (50)$$

Again the tower has cyclic steps and is unramified after finitely many steps; we find that it is dominated by the 3-class-field tower of the curve $\mathcal{X}_0(\wp_3^4)$.

Fantasia: a speculation on modularity. All our towers are of the following form: the bottom curve C_1 over some finite field k is equipped with an irreducible correspondence $\Phi \subset C_1 \times C_1$ of bidegree (l, l) and a set $S \subset C_1(k)$ of rational points each of which corresponds under Φ with l *distinct* points also in S ; the n -th curve in the tower is then the curve C_n of n -tuples $(P_1, \dots, P_n) \in C_1^n$ such that $(P_j, P_{j+1}) \in \Phi$ for $j = 1, 2, \dots, n - 1$. Then C_n has at least

$l^{n-1}|S|$ rational points, and at least when Φ is tamely ramified we can find the genus of C_n as a function of n . For instance, if $C_1 = X_0(l^2)$, Φ is the image of $X_0(l^3)$ under $\pi_0 \times \pi_1$, and S is the set of supersingular points, then we recover the tower of curves $X_0(l^{n+1})$ of our Proposition.

But the (C_1, Φ, S) description makes no assumption of modularity: we can, as in [GS2], try any C_1 and Φ and hope to find an S that yields many points on C_n . In fact, several such (C_1, Φ) were found to admit S large enough to make the tower $\{C_n\}$ asymptotically optimal [GS1,GS2]. However, in each such case $\{C_n\}$ was subsequently explained as a modular tower.

This leads us to speculate: perhaps every asymptotically optimal tower of this recursive form must be modular?

Acknowledgements. Thanks to H. Stichtenoth and P. Solé for e-mail correspondence on the explicit towers and AGM connections eventually published in [GS2] and [S1] respectively. Thanks also to J. Cazarán for reading the manuscript and spotting several local errors as the paper was going into print. Symbolic computations were greatly facilitated by the computer packages PARI and MACSYMA.

This work was made possible in part by funding from the National Science Foundation and the Packard Foundation.
